### Lab 04: Bayesian Classification

#### BACKGROUND.

The goal of this lab exercise is to implement the naïve Bayesian classification algorithm.

#### Task 1.

In this task you will again use the Titanic passenger dataset, which you can download from Canvas. The goal is to train a naïve Bayesian classifier for predicting survival based on gender and passenger class.

- A. Load the CSV file “titanic.csv” using Pandas. Extract the columns “Sex” and “Pclass” to use as feature vector, and the column “Survived” to use as target vector.
- B. Split the dataset into training and test data.
- C. Count the number of passenger, the number of survivors, and the number of casualties in the training data and calculate the priors  $P[\text{survived}]$  and  $P[\text{casualty}]$ .
- D. Count the number of male survivors, female survivors, male casualties, and female casualties in the training data and calculate the likelihoods  $P[\text{male}|\text{survived}]$ ,  $P[\text{female}|\text{survived}]$ ,  $P[\text{male}|\text{casualty}]$ ,  $P[\text{female}|\text{casualty}]$  applying Laplace smoothing with the parameter  $\alpha = 10$ .
- E. Count the number of 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> class survivors, and 1<sup>st</sup>, 2<sup>nd</sup>, and 3<sup>rd</sup> class casualties in the training data and calculate the likelihoods  $P[1\text{st class}|\text{survived}]$ ,  $P[2\text{nd class}|\text{survived}]$ ,  $P[3\text{rd class}|\text{survived}]$ ,  $P[1\text{st class}|\text{casualty}]$ ,  $P[2\text{nd class}|\text{casualty}]$ , and  $P[3\text{rd class}|\text{casualty}]$  applying Laplace smoothing with the parameter  $\alpha = 10$ .

#### Task 2.

In this task you will implement and evaluate the naïve Bayesian classifier for predicting survival based on gender and passenger class on the test set.

- A. Now go through all passengers in the test set and calculate the for each of these the posteriors  $P[\text{survived}|\text{sex}, \text{class}]$  and  $P[\text{casualty}|\text{sex}, \text{class}]$ . Make sure to use logarithms to guarantee numerical stability. Compare the likelihood-ratio to the prior-ratio to predict survival for each passenger in the test set.
- B. Calculate the confusion matrix to evaluate your classifier.
